Language processing performance of school-aged children and adults with phonological-syntactic dementia. The performance of 21 school-aged children and adults with phonological-syntactic dementia was compared with that of matched controls on a variety of language processing tasks. Subjects performed best on tasks that involved the processing of phonology, syntactic structure, and semantic information. The phonological-syntactic impairment of the children was comparable to that of the adults, and it was associated with a relatively spared semantic ability. The results suggested that the language impairment in these children may be a relatively pure deficit in the 2d92ce491b
