We report a case of acute respiratory distress syndrome induced by myocardial infarction and complicated with severe respiratory failure after emergency percutaneous coronary intervention and perioperative continuous venovenous hemodiafiltration (CVVHDF). The patient was a 71-year-old man with unstable angina and newly developed ST elevation in the inferior wall on his electrocardiogram. Emergency percutaneous coronary intervention was performed, but his symptoms improved only temporarily. After the operation, he complained of dyspnea and hypoxemia, and was referred to our hospital. On admission, his vital signs were as follows: blood pressure, 80/60 mmHg; pulse rate, 116/min; respiration rate, 21/min; and body temperature, 36.0 degrees C. The arterial blood gas analysis revealed the following: pH, 7.20; PaCO₂, 48.2 mmHg; PaO₂, 61.3 mmHg; bicarbonate, 9.8 mmol/L; HCO₃⁻ (24.3 mmol/L); and oxygen saturation, 93.8%. A chest X-ray showed severe bilateral infiltrates. Laboratory studies revealed the following: white blood cell count, 14,400/microL; hemoglobin, 13.0 g/dL; platelet count, 12.1 x 10⁴/microL; C-reactive protein (CRP), 6.63 mg/dL; lactate dehydrogenase, 454 U/L; creatine kinase-myocardial band (CK-MB), 69 ng/mL; brain natriuretic peptide (BNP), 2028 pg/mL; and troponin I, 0.01 microg/mL. An electrocardiogram revealed anterior ST-segment elevation. Emergent coronary angiography revealed total occlusion of the proximal left anterior descending artery and a thrombus in the proximal segment. After coronary angioplasty and intravenous administration of a glycoprotein IIb/IIIa inhibitor, aspiration thrombectomy and temporary heparin infusion

I was on a train which was moving upwards and the floor was made of steel. If there was a notch or a pit on the floor which increased the velocity of the floor -what would have happened if i jumped from there? For my surprise it is the right way to think. But why? I thought that velocity is additive. A: The three questions you are asking are: Is this correct? No, it is not. In order for something to move, you have to have more than one force acting upon it. If you want to jump and you want to jump a certain height, you need to have a certain number of "forces" acting on you (gravity, friction, air resistance, etc) in order to bring you to the necessary height. Why is this? Because force is the product of mass and acceleration. You are not accelerating, you are not changing your velocity, you are changing your mass. 1. Field of the Invention The present invention relates to a heat-developable photosensitive material. 2. Description of the Related Art Heretofore, many kinds of heat-developable photosensitive materials have been known. Among them, a heat-developable photosensitive material that includes a sheet-form substrate, a heat-generating layer formed on the substrate, and a photosensitive layer formed on the heat-generating layer, has such a structure as the photosensitive layer is formed after the heat-generating layer is formed. This type of heat-developable photosensitive material can be exposed imagewise to light and then developed in a heated state, thus producing a color image, for example, a black-and-white image or a color image. The heat-developable photosensitive material is therefore called a "dry silver-type" heat-developable photosensitive material. As the substrate of the heat-developable photosensitive material, a substrate of a polyester film has been known. The polyester film is used because of the following reasons. That is, the polyester film is inexpensive, excellent in mechanical properties 2d92ce491b
